

# Package ‘smerc’

January 16, 2021

**Type** Package

**Title** Statistical Methods for Regional Counts

**Version** 1.3.4

**Maintainer** Joshua French <joshua.french@ucdenver.edu>

**BugReports** <https://github.com/jfrench/smerc/issues>

**Description** Implements statistical methods for analyzing the counts of areal data, with a focus on the detection of spatial clusters and clustering. The package has a heavy emphasis on spatial scan methods, which were first introduced by Kulldorff and Nagarwalla (1995) <doi:10.1002/sim.4780140809> and Kulldorff (1997) <doi:10.1080/03610929708831995>.

**License** GPL (>= 2)

**LazyLoad** yes

**Depends** R (>= 3.6)

**Imports** pbapply, randtoolbox, sp, Rcpp

**Suggests** crayon, lintr, maps, testthat, SpatialEpi, knitr, rmarkdown

**Encoding** UTF-8

**RoxygenNote** 7.1.1

**VignetteBuilder** knitr

**LinkingTo** Rcpp, RcppProgress

**NeedsCompilation** yes

**Author** Joshua French [aut, cre] (<<https://orcid.org/0000-0002-9708-3353>>)

**Repository** CRAN

**Date/Publication** 2021-01-16 05:40:02 UTC

bn.test	<i>Besag-Newell Test</i>
---------	--------------------------

---

**Description**

bn.test implements the Besag-Newell test of Besag and Newell (1991) for finding disease clusters.

**Usage**

```
bn.test(
  coords,
  cases,
  pop,
  cstar,
  ex = sum(cases)/sum(pop) * pop,
  alpha = 0.1,
  longlat = FALSE,
  modified = FALSE
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
cstar	A non-negative integer indicating the minimum number of cases to include in each window.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
modified	A logical value indicating whether a modified version of the test should be performed. The original paper recommends computing the p-value for each cluster as $1 - \text{ppois}(cstar - 1, \lambda = \text{expected})$ . The modified version replaces cstar with cases, the observed number of cases in the region, and computes the p-value for the cluster as $1 - \text{ppois}(\text{cases} - 1, \lambda = \text{ex})$ . The default is modified = FALSE.

**Value**

Returns a `smerc_cluster` object.

**Author(s)**

Joshua French

**References**

**Examples**

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(x, y))
out = bn.test(coords = coords, cases = nydf$cases,
             pop = nydf$pop, cstar = 6,
             alpha = 0.1)
plot(out)
data(nypoly)
```

```
library(sp)
plot(nypoly, col = color.clusters(out))
```

---

bn.zones	<i>Determine case windows (circles)</i>
----------	---

---

### Description

bn.zones determines the case windows (circles) for the Besag-Newell method.

### Usage

```
bn.zones(d, cases, cstar)
```

```
casewin(d, cases, cstar)
```

### Arguments

d	An $n \times n$ square distance matrix containing the intercentroid distance between the $n$ region centroids.
cases	A vector of length $n$ containing the observed number of cases for the $n$ region centroids.
cstar	A non-negative integer indicating the minimum number of cases to include in each window.

### Details

Using the distances provided in `d`, for each observation, the nearest neighbors are included in increasingly larger windows until at least `cstar` cases are included in the window. Each row of `d` is matched with the same position in `cases`.

### Value

Returns the indices of the regions in each case window as a list. For each element of the list, the indices are ordered from nearest to farthest from each centroid (and include the starting region).

### Author(s)

Joshua French

### References

Besag, J. and Newell, J. (1991). The detection of clusters in rare diseases, *Journal of the Royal Statistical Society, Series A*, 154, 327-333.

## Examples

```
data(nydf)
coords = as.matrix(nydf[,c("longitude", "latitude")])
d = sp::spDists(coords, longlat = FALSE)
cwins = bn.zones(d, cases = nydf$cases, cstar = 6)
```

---

```
cepp.sim
```

```
Perform cepp.test on simulated data
```

---

## Description

`cepp.sim` efficiently performs `cepp.test` on a simulated data set. The function is meant to be used internally by the `cepp.test` function, but is informative for better understanding the implementation of the test.

## Usage

```
cepp.sim(nsim = 1, nn, ty, ex, wts, simdist = "multinomial")
```

## Arguments

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A list of nearest neighbors produced by <code>casewin</code> .
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>wts</code>	A list that has the weights associated with each region of each element of <code>nn</code> .
<code>simdist</code>	A character string indicating whether the simulated data should come from a "multinomial" or "poisson" distribution. The default is "multinomial", which fixes the total number of cases observed in each simulated data set.

## Value

A vector with the maximum test statistic for each simulated data set.

## Examples

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
d = sp::spDists(as.matrix(coords), longlat = TRUE)
nn = casewin(d, cases = nydf$pop, cstar = 15000)
cases = floor(nydf$cases)
ty = sum(cases)
ex = ty/sum(nydf$pop) * nydf$pop
# find smallest windows with at least n* pop
nstar = 1000
nn = casewin(d, cases = nydf$pop, cstar = nstar)
```

```
# determine ts
wts = cepp.weights(nn, nydf$pop, nstar)
tsim = cepp.sim(1, nn = nn, ty = ty, ex = ex, wts = wts)
```

cepp.test

*Cluster Evaluation Permutation Procedure Test***Description**

cepp.test implements the Cluster Evaluation Permutation Procedure test of Turnbull et al. (1990) for finding disease clusters.

**Usage**

```
cepp.test(
  coords,
  cases,
  pop,
  nstar,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  longlat = FALSE,
  simdist = "multinomial"
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
nstar	The size of the at-risk population in each window.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
simdist	A character string indicating whether the simulated data should come from a "multinomial" or "poisson" distribution. The default is "multinomial", which fixes the total number of cases observed in each simulated data set.

**Value**

Returns a `smerc_cluster` object.

**See Also**

[print.smerc\\_cluster](#), [summary.smerc\\_cluster](#), [plot.smerc\\_cluster](#), [scan.test](#)

**Examples**

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(x, y))
cases = nydf$cases
pop = nydf$pop
out = cepp.test(coords = coords, cases = cases, pop = pop,
               nstar = 1000, alpha = 0.1)
plot(out)

data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

---

cepp.weights

*Compute region weights for cepp.test*

---

**Description**

Compute region weights for `cepp.test`

**Usage**

```
cepp.weights(nn, pop, nstar)
```

**Arguments**

<code>nn</code>	A list of nearest neighbors produced by <code>casewin</code> .
<code>pop</code>	The population size associated with each region.
<code>nstar</code>	The size of the at-risk population in each window.

**Value**

A list with elements related to the weight each nearest neighbor region will have in the corresponding weighted sum used to compute the test statistic

**Examples**

```
data(nydf)
coords = with(nydf, cbind(x, y))
pop = nydf$pop
# intercentroid distances
d = sp::spDists(coords)
# find smallest windows with cumulative population of
# at least n* = 1000
nn = casewin(d, pop, 1000)
# compute weights
w = cepp.weights(nn, pop, 1000)
```

---

color.clusters

*Color clusters*

---

**Description**

color.clusters is a helper function to color clusters of regions produced by an appropriate method, e.g., scan.test or uls.test. Regions that are not part of any cluster have no color.

**Usage**

```
color.clusters(x, col = grDevices::hcl.colors(length(x$clusters)))
```

**Arguments**

**x** An object of class scan produced by a function such as scan.test.

**col** A vector of colors to color the clusters in x. Should have same length as the number of clusters in x.

**Value**

Returns a vector with colors for each region/centroid for the data set used to construct x.

**Author(s)**

Joshua French

## Examples

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
out = scan.test(coords = coords, cases = floor(nydf$cases),
               pop = nydf$pop, alpha = 0.12, longlat = TRUE,
               nsim = 9)
data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

---

combine.zones	<i>Combine distinct zones</i>
---------------	-------------------------------

---

## Description

combine.zones combines the elements of z1 and z2 into a single list, returning only the unique zones.

## Usage

```
combine.zones(z1, z2)
```

## Arguments

z1	A list of zones
z2	A list of zones

## Value

A list of distinct zones

## Examples

```
z1 = list(1:2, 1:3)
z2 = list(2:1, 1:4)
combine.zones(z1, z2)
```

**Description**

csg2, lcsg2, and scsg2 construct connected subgraphs. These functions are not intended for users. nn contains a list of nearest neighbors for each region. idx is a vector of possible vertices being considered as a subgraph. w is a connectivity matrix relating the N vertices.  $w[i, j] = 1$  if vertices i and j are connected, i.e., if they share an edge. The dimensions of w are  $N \times k$ , where  $k = \text{length}(\text{idx})$ . While the rows of w contain adjacency information for all N vertices, only the idx columns of the complete adjacency matrix are used in w. See Details for discussion of scsg.

**Usage**

```
csg2(cz, cnn, cw)

lcsg2(lcz, cnn, cw)

scsg2(
  nn,
  w,
  idx = seq_along(nn),
  nlevel = NULL,
  verbose = FALSE,
  logical = FALSE
)
```

**Arguments**

cz	A logical vector representing the current subgraph.
cnn	The indices of the neighbors of the current vertex.
cw	A binary adjacency matrix for the neighbors of the current vertex.
lcz	A list of current zones (in the form of logical vectors).
nn	A list of the nearest neighbors for each vertex (region).
w	A binary adjacency matrix indicating connected neighbors.
idx	A vector of vertices for which to construct the set of connected subgraphs.
nlevel	The maximum size of each subgraph.
verbose	A logical value indicating whether descriptive messages should be provided. Default is FALSE. If TRUE, this can be useful for diagnosing where the sequences of connected subgraphs is slowing down/having problems.
logical	A logical value indicating whether a list of logical vectors should be returned. The default is FALSE, indicating that the scsg function should return a list of vectors with each vector containing the vertex indices included in each subgraph.

## Details

scsg2 performs a sequence of lcs2 calls. Starting with lcz == list(idx[1]), scsg keeps iteratively building more connected subgraphs by performing something like: lcz1 = list(idx[1]). lcz2 = lcs2(lcz1, ...). lcz3 = lcs2(lcz2, ...). This is done until there are no more connected subgraphs among the elements of idx.

## Value

A list with all possible connected subgraphs based on the user-provided parameters.

## Examples

```
data(nydf)
data(nyw)
# determine 50 nn of region 1 for NY data
coords = as.matrix(nydf[,c("longitude", "latitude")])
nn3 = knn(coords, longlat = TRUE, k = 3)
z1 = scsg2(nn3, nyw)
z2 = flex.zones(coords, nyw, k = 3, longlat = TRUE)
all.equal(z1, z2)
```

---

dc.sim

*Perform dc.test on simulated data*

---

## Description

dc.sim efficiently performs `dc.test` on a simulated data set. The function is meant to be used internally by the `dc.test` function, but is informative for better understanding the implementation of the test.

## Usage

```
dc.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

## Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Value**

A vector with the maximum test statistic for each simulated data set.

**Examples**

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
d = sp::spDists(coords, longlat = TRUE)
nn = nndist(d, ubd = 0.05)
max_pop = sum(pop) * 0.25
tsim = dc.sim(1, nn, ty, ex, nyw, pop = pop,
             max_pop = max_pop)
```

---

dc.test

---

*Double Connection spatial scan test*

---

**Description**

dc.test implements the Double Connection spatial scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic, with the added constraint that the region must have at least two connection (i.e., shares a border with) at least two of the regions in the current zone. This procedure is repeated until adding a connected region does not increase the test statistic (or the population or distance upper bounds are reached). The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

**Usage**

```
dc.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Details**

The maximum intercentroid distance can be found by executing the command: `sp::spDists(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

**Value**

Returns a `smerc_cluster` object.

**Examples**

```

data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
out = dc.test(coords = coords, cases = floor(nydf$cases),
             pop = nydf$population, w = nyw,
             alpha = 0.12, longlat = TRUE,
             nsim = 5, ubpop = 0.1, ubd = 0.2)

data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))

```

---

dc.zones

*Determine zones for the Double Connected scan test*

---

**Description**

dc.zones determines the zones for the Double Connected scan test ([dc.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

**Usage**

```

dc.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)

```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

### Details

Every zone considered must have a total population less than  $ubpop * \text{sum}(\text{pop})$ . Additionally, the maximum intercentroid distance for the regions within a zone must be no more than  $ubd * \text{the maximum intercentroid distance across all regions}$ .

### Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

### Author(s)

Joshua French

### References

Costa, M.A. and Assuncao, R.M. and Kulldorff, M. (2012) Constrained spanning tree algorithms for irregularly-shaped spatial clustering, *Computational Statistics & Data Analysis*, 56(6), 1771-1783. <doi:10.1016/j.csda.2011.11.001>

### Examples

```
data(nydf)
data(nyw)
coords = as.matrix(nydf[,c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones = dc.zones(coords, cases = floor(nydf$cases),
                    nydf$pop, w = nyw, ubpop = 0.25,
                    ubd = .25, longlat = TRUE)
```

---

dist.ellipse	<i>Compute minor axis distance of ellipse</i>
--------------	---

---

**Description**

dist.ellipse computes the length of the minor axis needed for an ellipse of a certain shape and angle to intersect each of the other coordinates from a starting coordinate.

**Usage**

```
dist.ellipse(coords, shape, angle)
```

**Arguments**

coords	An $N \times 2$ matrix of coordinates
shape	The ratio of the major axis to the minor axis of the ellipse
angle	The angle of the ellipse in the range [0, 180).

**Value**

A matrix of distances between each coordinate and all other coordinates (and itself). Each row contains the distances for a coordinate.

**Examples**

```
data(nydf)
coords = as.matrix(nydf[,c("x", "y")])
d = dist.ellipse(coords, 4, 15)
```

---

distinct	<i>Distinct elements of a list</i>
----------	------------------------------------

---

**Description**

distinct takes a list of integer vectors and returns the list indices that contain unique combinations of elements. This function is NOT robust against misuse, so please use properly.

**Usage**

```
distinct(x, N = max(unlist(x)))
```

**Arguments**

x	A list of integers
N	The largest integer value across all elements of x.

**Details**

Assume that  $k$  is the largest integer value in  $x$ . A vector of the largest  $k$  prime numbers is obtained (call this `pri`). The algorithm takes the sum of the log of `pri[x[[i]]]` for each element of  $x$ , and determines which sums are unique. This is why the elements of  $x$  must be integer vectors. The prime aspect of the algorithm is critical, as it ensures that a none of the values are multiples of the others, ensuring uniqueness.

Note: this algorithm has only been applied to data sets where each element of `x[[i]]` appears only once, though it should work for repeats also.

**Value**

A vector with the distinct indices.

**Author(s)**

Joshua French

Algorithm based on suggestion at <https://stackoverflow.com/a/29824978>.

**Examples**

```
x = list(1:3, 3:1, 1:4, 4:1, c(1, 2, 4, 6), c(6, 4, 1, 2))
x[distinct(x)]
```

---

dmst.sim

*Perform dmst.test on simulated data*

---

**Description**

`dmst.sim` efficiently performs `dmst.test` on a simulated data set. The function is meant to be used internally by the `dmst.test` function, but is informative for better understanding the implementation of the test.

**Usage**

```
dmst.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

**Arguments**

<code>nsim</code>	A positive integer indicating the number of simulations to perform.
<code>nn</code>	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
<code>ty</code>	The total number of cases in the study area.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.

w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Value

A vector with the maximum test statistic for each simulated data set.

### Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
d = sp::spDists(coords, longlat = TRUE)
nn = nndist(d, ubd = 0.05)
max_pop = sum(pop) * 0.25
tsim = dmst.sim(1, nn, ty, ex, nyw, pop = pop,
               max_pop = max_pop)
```

---

dmst.test

*Dynamic Minimum Spanning Tree spatial scan test*

---

### Description

`dmst.test` implements the dynamic Minimum Spanning Tree scan test of Assuncao et al. (2006). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic. This procedure is repeated until the population or distance upper bounds are reached. The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

### Usage

```
dmst.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
```

```

nsim = 499,
alpha = 0.1,
ubpop = 0.5,
ubd = 1,
longlat = FALSE,
cl = NULL
)

```

### Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Details

The maximum intercentroid distance can be found by executing the command: `sp::spDists(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

### Value

Returns a `smerc_cluster` object.

### Author(s)

Joshua French

### References

**Examples**

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
out = dmst.test(coords = coords, cases = floor(nydf$cases),
               pop = nydf$pop, w = nyw,
               alpha = 0.12, longlat = TRUE,
               nsim = 2, ubpop = 0.05, ubd = 0.1)
data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

---

dmst.zones

*Determine zones for the Dynamic Minimum Spanning Tree scan test*

---

**Description**

`dmst.zones` determines the zones for the Dynamic Minimum Spanning Tree scan test ([dmst.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

**Usage**

```
dmst.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)
```

**Arguments**

<code>coords</code>	An $n \times 2$ matrix of centroid coordinates for the regions.
<code>cases</code>	The number of cases observed in each region.
<code>pop</code>	The population size associated with each region.
<code>w</code>	A binary spatial adjacency matrix for the regions.

ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

### Details

Every zone considered must have a total population less than  $ubpop * \text{sum}(\text{pop})$ . Additionally, the maximum intercentroid distance for the regions within a zone must be no more than  $ubd * \text{the maximum intercentroid distance across all regions}$ .

### Value

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

### Examples

```
data(nydf)
data(nyw)
coords = as.matrix(nydf[,c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones = dmst.zones(coords, cases = floor(nydf$cases),
                      nydf$pop, w = nyw, ubpop = 0.25,
                      ubd = .25, longlat = TRUE)
```

---

edmst.sim	<i>Perform edmst.test on simulated data</i>
-----------	---

---

## Description

edmst.sim efficiently performs `edmst.test` on a simulated data set. The function is meant to be used internally by the `edmst.test` function, but is informative for better understanding the implementation of the test.

## Usage

```
edmst.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

## Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

## Value

A vector with the maximum test statistic for each simulated data set.

## Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
d = sp::spDists(coords, longlat = TRUE)
nn = nndist(d, ubd = 0.05)
max_pop = sum(pop) * 0.25
tsim = edmst.sim(1, nn, ty, ex, nyw, pop = pop,
                max_pop = max_pop)
```

---

edmst.test

*Early Stopping Dynamic Minimum Spanning Tree spatial scan test*

---

## Description

edmst.test implements the early stopping dynamic Minimum Spanning Tree scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic. This procedure is repeated until adding a connected region does not increase the test statistic (or the population or distance upper bounds are reached). The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

## Usage

```
edmst.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

## Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
c1	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Details

The maximum intercentroid distance can be found by executing the command: `sp::spDists(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

### Value

Returns a `smerc_cluster` object.

edmst.zones	<i>Determine zones for the early stopping dynamic Minimum Spanning Tree scan test</i>
-------------	---

---

## Description

edmst.zones determines the zones for the early stopping Dynamic Minimum Spanning Tree scan test ([edmst.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

## Usage

```
edmst.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)
```

## Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see <a href="#">Details on performance</a> ).
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

**Details**

Every zone considered must have a total population less than  $ubpop * \text{sum}(\text{pop})$ . Additionally, the maximum intercentroid distance for the regions within a zone must be no more than  $ubd * \text{the maximum intercentroid distance across all regions}$ .

**Value**

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

**Examples**

```
data(nydf)
data(nyw)
coords = as.matrix(nydf[,c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones = edmst.zones(coords, cases = floor(nydf$cases),
                        nydf$pop, w = nyw, ubpop = 0.25,
                        ubd = .25, longlat = TRUE)
```

---

elliptic.nn

*Nearest neighbors for elliptic scan*

---

**Description**

elliptic.nn computes the nearest neighbors relationships for elliptic.test. It will provide a list of nearest neighbors, and a list of the associated shape and angle.

**Usage**

```
elliptic.nn(
  coords,
  pop,
  ubpop = 0.5,
  shape = c(1, 1.5, 2, 3, 4, 5),
  nangle = c(1, 4, 6, 9, 12, 15)
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
shape	The ratios of the major and minor axes of the desired ellipses.
nangle	The number of angles (between 0 and 180) to consider for each shape.

**Value**

A list of nested nearest neighbors, the associated shapes and angles for each set of nn, and all of the shapes and angles you get for each zone constructed from the set of nearest neighbors.

**Examples**

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
enn = elliptic.nn(coords, nydf$pop, 0.1,
  shape = c(1, 1.5), nangle = c(1, 4))
```

---

elliptic.sim

---

*Perform elliptic.test on simulated data*

---

**Description**

elliptic.sim efficiently performs [elliptic.test](#) on a simulated data set. The function is meant to be used internally by the [elliptic.test](#) function, but is informative for better understanding the implementation of the test.

**Usage**

```
elliptic.sim(nsim = 1, nn, ty, ex, a, shape_all, ein, eout, cl = NULL)
```

**Arguments**

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of nearest neighbors produced by <code>elliptic.nn</code> .
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
a	The penalty for the spatial scan statistic. The default is 0.5.
shape_all	A vector of the shapes associated with all of the possible zones constructed from nn. This can be obtained from <code>elliptic.nn</code> .
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be <code>ty - ein</code> and is computed automatically if not provided.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Value**

A vector with the maximum test statistic for each simulated data set.

**Examples**

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
pop = nydf$pop
enn = elliptic.nn(coords, pop, ubpop = 0.1,
                  shape = c(1, 1.5), nangle = c(1, 4))
cases = floor(nydf$cases)
ty = sum(cases)
ex = ty/sum(pop) * pop
yin = nn.cumsum(enn$nn, cases)
ein = nn.cumsum(enn$nn, ex)
tsim = elliptic.sim(nsim = 2, nn = enn$nn, ty = ty, ex = ex,
                   a = 0.5, shape_all = enn$shape_all,
                   ein = ein, eout = ty - ein)
```

---

elliptic.test

*Elliptical Spatial Scan Test*

---

**Description**

`elliptic.test` performs the elliptical scan test of Kulldorf et al. (2006).

**Usage**

```
elliptic.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  shape = c(1, 1.5, 2, 3, 4, 5),
  nangle = c(1, 4, 6, 9, 12, 15),
  a = 0.5,
  cl = NULL,
  type = "poisson",
  min.cases = 2
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
shape	The ratios of the major and minor axes of the desired ellipses.
nangle	The number of angles (between 0 and 180) to consider for each shape.
a	The penalty for the spatial scan statistic. The default is 0.5.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
min.cases	The minimum number of cases required for a cluster. The default is 2.

**Details**

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. Candidate zones are elliptical and extend from the observed data locations. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

**Value**

Returns a `smerc_cluster` object.

coords = with(nydf, cbind(longitude, latitude))
out = elliptic.test(coords = coords,
                   cases = floor(nydf$cases),
                   pop = nydf$pop, ubpop = 0.1,
                   nsim = 2,
                   alpha = 0.12,
                   shape = 1.5, nangle = 4)
```

---

elliptic.zones

*Determine zones for elliptic.test*

---

**Description**

`elliptic.zones` constructs the elliptical zones for [elliptic.test](#).

**Usage**

```
elliptic.zones(
  coords,
  pop,
  ubpop = 0.5,
  shape = c(1, 1.5, 2, 3, 4, 5),
  nangle = c(1, 4, 6, 9, 12, 15)
)
```

### Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
shape	The ratios of the major and minor axes of the desired ellipses.
nangle	The number of angles (between 0 and 180) to consider for each shape.

### Value

A list with all distinct zones, the associated shape parameters, and the associated angle parameters.

### References

Kulldorff, M., Huang, L., Pickle, L. and Duczmal, L. (2006) An elliptic spatial scan statistic. *Statistics in Medicine*, 25:3929-3943. <doi:10.1002/sim.2490>

### Examples

```
## Not run:
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
out = elliptic.zones(coords = coords, pop = nydf$pop,
                    shape = 1.5, nangle = 4)
## End(Not run)
```

---

fast.sim

*Perform fast.test on simulated data*

---

### Description

fast.sim efficiently performs [fast.test](#) on a simulated data set. The function is meant to be used internally by the [fast.test](#) function, but is informative for better understanding the implementation of the test.

### Usage

```
fast.sim(nsim = 1, ty, ex, pop, ubpop, type = "poisson", cl = NULL)
```

**Arguments**

nsim	A positive integer indicating the number of simulations to perform.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Value**

A vector with the maximum test statistic for each simulated data set.

**Examples**

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
tsim = fast.sim(1, ty, ex, pop = pop, ubpop = 0.5)
```

---

fast.test

*Fast Subset Scan Test*

---

**Description**

fast.test performs the fast subset scan test of Neill (2012).

**Usage**

```
fast.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
```

```

    cl = NULL,
    type = "poisson"
)

```

### Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".

### Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The windows are based on the Upper Level Sets proposed by Patil and Taillie (2004). The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

### Value

Returns a list of length two of class `scan`. The first element (`clusters`) is a list containing the significant, non-overlapping clusters, and has the following components:

locids	The location ids of regions in a significant cluster.
pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

**Examples**

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
out = fast.test(coords = coords, cases = floor(nydf$cases),
               pop = nydf$pop,
               alpha = 0.05, longlat = TRUE,
               nsim = 49, ubpop = 0.5)
```

---

fast.zones

*Determine sequence of fast subset scan zones*

---

**Description**

fast.zones determines the unique zones obtained by implementing the fast subset scan method of Neill (2012).

**Usage**

```
fast.zones(cases, pop, ubpop = 0.5, simple = TRUE)
```

**Arguments**

cases	The number of cases observed in each region.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
simple	A logical value indicating whether a simple version of the fast zones should be returned. See Details.

### Details

The `simple` argument determines the formatting of the returned zones. If `simple = TRUE`, then a vector containing the sequential indices of the regions in each successive zones is returned. If `simple = FALSE`, then the complete list of all zones is returned (which is the standard format of most of the other `*.zones` functions).

The zones returned must have a total population less than `ubpop * sum(pop)` of all regions in the study area.

### Value

Returns a vector of regions to sequentially and cumulatively consider for clustering.

### Author(s)

Joshua French

### References

Neill, D. B. (2012), Fast subset scan for spatial pattern detection. *Journal of the Royal Statistical Society: Series B (Statistical Methodology)*, 74: 337-360. <doi:10.1111/j.1467-9868.2011.01014.x>

### Examples

```
data(nydf)
cases = nydf$cases
pop = nydf$pop
# compare output format
fast.zones(cases, pop, ubpop = 0.05)
fast.zones(cases, pop, ubpop = 0.05, simple = FALSE)
```

---

flex.sim

*Perform flex.test on simulated data*

---

### Description

`flex.sim` efficiently performs `flex.test` on a simulated data set. The function is meant to be used internally by the `flex.test` function, but is informative for better understanding the implementation of the test.

### Usage

```
flex.sim(
  nsim = 1,
  zones,
  ty,
  ex,
  type = "poisson",
```

```

    ein = NULL,
    eout = NULL,
    tpop = NULL,
    popin = NULL,
    popout = NULL,
    cl = NULL
  )

```

## Arguments

nsim	A positive integer indicating the number of simulations to perform.
zones	A list of zones to compute the test statistic over for each simulated data set.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be $ty - ein$ and is computed automatically if not provided.
tpop	The total population in the study area.
popin	The total population in the zone.
popout	The population outside the zone. This should be $tpop - popin$ and is computed automatically if not provided.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see <a href="#">Details on performance</a> ).

## Value

A vector with the maximum test statistic for each simulated data set.

## Examples

```

data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
zones = flex.zones(coords, w = nyw, k = 3, longlat = TRUE)
cases = floor(nydf$cases)
ty = sum(cases)
ex = ty/sum(nydf$pop) * nydf$pop
ein = zones.sum(zones, ex)
tsim = flex.sim(nsim = 2, zones, ty, ex, ein = ein, eout = ty - ein)

```

flex.test

*Flexibly-shaped Spatial Scan Test***Description**

flex.test performs the flexibly-shaped scan test of Tango and Takahashi (2005).

**Usage**

```
flex.test(
  coords,
  cases,
  pop,
  w,
  k = 10,
  ex = sum(cases)/sum(pop) * pop,
  type = "poisson",
  nsim = 499,
  alpha = 0.1,
  longlat = FALSE,
  cl = NULL,
  lonlat = longlat,
  ...
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.

cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
lonlat	Deprecated in favor of <code>longlat</code> .
...	Not used.

## Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

## Value

Returns a list of length two of class `scan`. The first element (`clusters`) is a list containing the significant, non-overlapping clusters, and has the the following components:

data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
out = flex.test(coords = coords, cases = floor(nydf$cases),
               w = nyw, k = 3,
               pop = nydf$pop, nsim = 49,
               alpha = 0.12, longlat = TRUE)

data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

flex.zones

*Determine zones for flexibly shaped spatial scan test***Description**

flex.zones determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2005). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size  $k$  or less.

**Usage**

```
flex.zones(
  coords,
  w,
  k = 10,
  longlat = FALSE,
  cl = NULL,
  loop = FALSE,
  verbose = FALSE,
  pfreq = 1
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see <a href="#">Details on performance</a> ).
loop	A logical value indicating whether a loop should be used to implement the function instead of <a href="#">pbapply</a> . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both loop and verbose are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if verbose = TRUE). The default is pfreq = 1, meaning a message is returned for each index of the loop.

**Value**

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

**Author(s)**

Joshua French

**References**

Tango, T., & Takahashi, K. (2005). A flexibly shaped spatial scan statistic for detecting clusters. *International journal of health geographics*, 4(1), 11.

data(nyw)
coords = cbind(nydf$x, nydf$y)
zones = flex.zones(coords, w = nyw, k = 3)
## Not run:
# see what happens when verbose = TRUE
zones = flex.zones(coords, w = nyw, k = 3, verbose = TRUE)

## End(Not run)
```

---

flex\_test

*Flexibly-shaped Spatial Scan Test*

---

**Description**

flex\_test performs the flexibly-shaped scan test of Tango and Takahashi (2005).

**Usage**

```
flex_test(
  coords,
  cases,
  pop,
  w,
  k = 10,
  ex = sum(cases)/sum(pop) * pop,
  type = "poisson",
  nsim = 499,
  alpha = 0.1,
  longlat = FALSE,
  cl = NULL,
  lonlat = longlat,
  ...
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
lonlat	Deprecated in favor of longlat.
...	Not used.

**Details**

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

**Value**

Returns a list of length two of class scan. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the the following components:

---

flex\_zones

*Determine zones for flexibly shaped spatial scan test*

---

**Description**

`flex_zones` determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2005). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size  $k$  or less.

**Usage**

```
flex_zones(
  coords,
  w,
  k = 10,
  longlat = FALSE,
  cl = NULL,
  loop = FALSE,
  verbose = FALSE,
  pfreq = 1
)
```

**Arguments**

<code>coords</code>	An $n \times 2$ matrix of centroid coordinates for the regions.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>k</code>	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10

longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	Ignored, but retained for backwards compatibility
loop	A logical value indicating whether a loop should be used to implement the function instead of <code>pbapply</code> . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both loop and verbose are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if verbose = TRUE). The default is pfreq = 1, meaning a message is returned for each index of the loop.

### Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

### Author(s)

Joshua French

### References

Tango, T., & Takahashi, K. (2005). A flexibly shaped spatial scan statistic for detecting clusters. *International journal of health geographics*, 4(1), 11.

### Examples

```
data(nydf)
data(nyw)
coords = cbind(nydf$x, nydf$y)
zones = flex_zones(coords, w = nyw, k = 3)
## Not run:
# see what happens when verbose = TRUE
zones = flex_zones(coords, w = nyw, k = 3, verbose = TRUE)

## End(Not run)
```

---

knn *K nearest neighbors*

---

### Description

knn returns the k nearest neighbors of the n coordinates in coords. The nearest neighbors are constructed to be self-inclusive, i.e., an observations is its closest neighbor.

### Usage

```
knn(coords, longlat = FALSE, k = 1, d = NULL)
```

### Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
d	An n by n distance matrix. If provided, this is used instead of computing d based on coords and longlat.

### Value

An  $n \times k$  matrix of nearest neighbors.

### Examples

```
data(nydf)
coords = nydf[,c("longitude", "latitude")]
knn(coords, longlat = TRUE, k = 4)
```

---

lget *Apply getElement over a list*

---

### Description

lget or lgetElement applies getElement to a list using [lapply](#). sget and sgetElement do the same thing with sapply.

**Usage**

```
lget(X, name)

lgetElement(X, name)

sget(X, name, simplify = TRUE, USE.NAMES = TRUE)

sgetElement(X, name, simplify = TRUE, USE.NAMES = TRUE)
```

**Arguments**

X	A list.
name	A literal character string or a <a href="#">name</a> (possibly <a href="#">backtick</a> quoted). For extraction, this is normally (see under ‘Environments’) partially matched to the <a href="#">names</a> of the object.
simplify	logical or character string; should the result be simplified to a vector, matrix or higher dimensional array if possible? For sapply it must be named and not abbreviated. The default value, TRUE, returns a vector or matrix if appropriate, whereas if simplify = "array" the result may be an <a href="#">array</a> of “rank” (=length(dim(.))) one higher than the result of FUN(X[[i]]).
USE.NAMES	logical; if TRUE and if X is character, use X as <a href="#">names</a> for the result unless it had names already. Since this argument follows . . . its name cannot be abbreviated.

**Value**

A list (lget) or vector (sget) of the same length as X with the name parts of each element of X.

**Examples**

```
e1 = list(x = rnorm(5),
         y = letters[c(1:2, 2:1, 3)],
         z = c(TRUE, TRUE, FALSE, TRUE, TRUE)
)
e2 = list(x = rnorm(5),
         y = letters[c(1:4, 1)],
         z = c(FALSE, TRUE, FALSE, TRUE, FALSE))
X = list(e1, e2)
lget(X, name = "x")
sget(X, name = "y")
```

## Description

`mlf.test` implements the Maxima Likelihood First scan test of Yao et al. (2011), which is actually a special case of the Dynamic Minimum Spanning Tree of Assuncao et al. (2006). Find the single region that maximizes the likelihood ratio test statistic. Starting with this single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the likelihood ratio test statistic. This procedure is repeated until the population and/or distance upper bound is reached.

## Usage

```
mlf.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 0.5,
  longlat = FALSE,
  cl = NULL
)
```

## Arguments

<code>coords</code>	An $n \times 2$ matrix of centroid coordinates for the regions.
<code>cases</code>	The number of cases observed in each region.
<code>pop</code>	The population size associated with each region.
<code>w</code>	A binary spatial adjacency matrix for the regions.
<code>ex</code>	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
<code>nsim</code>	The number of simulations from which to compute the p-value.
<code>alpha</code>	The significance level to determine whether a cluster is significant. Default is 0.10.
<code>ubpop</code>	The upperbound of the proportion of the total population to consider for a cluster.
<code>ubd</code>	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
<code>longlat</code>	The default is FALSE, which specifies that Euclidean distance should be used. If <code>longlat</code> is TRUE, then the great circle distance is used to calculate the intercentroid distance.
<code>cl</code>	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Details**

Only a single candidate zone is ever returned because the algorithm only constructs a single sequence of starting zones, and overlapping zones are not returned. Only the zone that maximizes the likelihood ratio test statistic is returned.

**Value**

Returns a list of length two of class `scan`. The first element (`clusters`) is a list containing the significant, non-overlapping clusters, and has the following components:

<code>locids</code>	The location ids of regions in a significant cluster.
<code>pop</code>	The total population in the cluster window.
<code>cases</code>	The observed number of cases in the cluster window.
<code>expected</code>	The expected number of cases in the cluster window.
<code>smr</code>	Standardized mortality ratio (observed/expected) in the cluster window.
<code>rr</code>	Relative risk in the cluster window.
<code>loglikrat</code>	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
<code>pvalue</code>	The pvalue of the test statistic associated with the cluster window.
<code>w</code>	The adjacency matrix of the cluster.
<code>r</code>	The maximum radius of the cluster (in terms of intercentroid distance from the starting region).

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

```

---

mLf.zones

*Determine zones for the maxima likelihood first algorithm.*

---

### Description

mLf.zones determines the most likely cluster zone obtained by implementing the maxima likelihood first scann method of Yao et al. (2011). Note that this is really just a special case of the dynamic minimum spanning tree (DMST) algorithm of Assuncao et al. (2006)

### Usage

```

mLf.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE
)

```

### Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.

## Details

Each step of the mlf scan test seeks to maximize the likelihood ratio test statistic used in the original spatial scan test (Kulldorff 1997). The first zone considered is the region that maximizes this likelihood ratio test statistic, providing that no more than `ubpop` proportion of the total population is in the zone. The second zone is the first zone and the connected region that maximizes the scan statistic, subject to the population and distance constraints. This pattern continues until no additional zones can be added due to population or distance constraints.

Every zone considered must have a total population less than `ubpop * sum(pop)` in the study area. Additionally, the maximum intercentroid distance for the regions within a zone must be no more than `ubd * the maximum intercentroid distance across all regions`.

## Value

Returns a list with elements:

<code>zones</code>	A list contained the location ids of each potential cluster.
<code>loglikrat</code>	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
<code>cases</code>	The observed number of cases in each zone.
<code>expected</code>	The expected number of cases each zone.
<code>pop</code>	The total population in each zone.

Yao, Z., Tang, J., & Zhan, F. B. (2011). Detection of arbitrarily-shaped clusters using a neighbor-expanding approach: A case study on murine typhus in South Texas. *International Journal of Health Geographics*, 10(1), 1.

## Examples

```
data(nydf)
data(nyw)
coords = as.matrix(nydf[,c("x", "y")])
mlf.zones(coords, cases = floor(nydf$cases),
          pop = nydf$pop, w = nyw, longlat = TRUE)
```

---

mlink.sim	<i>Perform mlink.test on simulated data</i>
-----------	---

---

### Description

mlink.sim efficiently performs `mlink.test` on a simulated data set. The function is meant to be used internally by the `mlink.test` function, but is informative for better understanding the implementation of the test.

### Usage

```
mlink.sim(nsim = 1, nn, ty, ex, w, pop, max_pop, cl = NULL)
```

### Arguments

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of distance-based nearest neighbors, preferably from the <code>nndist</code> function.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.
pop	The population size associated with each region.
max_pop	The population upperbound (in total population) for a candidate zone.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Value

A vector with the maximum test statistic for each simulated data set.

### Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
d = sp::spDists(coords, longlat = TRUE)
nn = nndist(d, ubd = 0.05)
max_pop = sum(pop) * 0.25
tsim = mlink.sim(1, nn, ty, ex, nyw, pop = pop,
                 max_pop = max_pop)
```

mlink.test

*Maximum Linkage spatial scan test***Description**

mlink.test implements the Maximum Linkage spatial scan test of Costa et al. (2012). Starting with a single region as a current zone, new candidate zones are constructed by combining the current zone with the connected region that maximizes the resulting likelihood ratio test statistic, with the added constraint that the region has the maximum connections (i.e., shares a border with) with the regions in the current zone. This procedure is repeated until the population or distance upper bounds constraints are reached. The same procedure is repeated for each region. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

**Usage**

```
mlink.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
c1	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Details

The maximum intercentroid distance can be found by executing the command: `sp::spDists(as.matrix(coords), longlat = longlat)`, based on the specified values of `coords` and `longlat`.

### Value

Returns a `smerc_cluster` object.

### Author(s)

Joshua French

### References

Costa, M.A. and Assuncao, R.M. and Kulldorff, M. (2012) Constrained spanning tree algorithms for irregularly-shaped spatial clustering, *Computational Statistics & Data Analysis*, 56(6), 1771-1783. <doi:10.1016/j.csda.2011.11.001>

### Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
out = mLink.test(coords = coords, cases = floor(nydf$cases),
                pop = nydf$pop, w = nyw,
                alpha = 0.12, longlat = TRUE,
                nsim = 2, ubpop = 0.05, ubd = 0.1)

data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

mlink.zones

*Determine zones for the Maximum Linkage scan test***Description**

mlink.zones determines the zones for the Maximum Linkage scan test ([mlink.test](#)). The function returns the zones, as well as the associated test statistic, cases in each zone, the expected number of cases in each zone, and the population in each zone.

**Usage**

```
mlink.zones(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
  ubpop = 0.5,
  ubd = 1,
  longlat = FALSE,
  cl = NULL,
  progress = TRUE
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the intercentroid distance.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see <a href="#">Details on performance</a> ).
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

**Details**

Every zone considered must have a total population less than  $ubpop * \text{sum}(\text{pop})$ . Additionally, the maximum intercentroid distance for the regions within a zone must be no more than  $ubd * \text{the maximum intercentroid distance across all regions}$ .

**Value**

Returns a list with elements:

zones	A list contained the location ids of each potential cluster.
loglikrat	The loglikelihood ratio for each zone (i.e., the log of the test statistic).
cases	The observed number of cases in each zone.
expected	The expected number of cases each zone.
pop	The total population in each zone.

Costa, M.A. and Assuncao, R.M. and Kulldorff, M. (2012) Constrained spanning tree algorithms for irregularly-shaped spatial clustering, *Computational Statistics & Data Analysis*, 56(6), 1771-1783. <doi:10.1016/j.csda.2011.11.001>

**Examples**

```
data(nydf)
data(nyw)
coords = as.matrix(nydf[,c("longitude", "latitude")])
# find zone with max statistic starting from each individual region
all_zones = mlink.zones(coords, cases = floor(nydf$cases),
                        nydf$pop, w = nyw, ubpop = 0.25,
                        ubd = .25, longlat = TRUE)
```

---

mst.all

*Minimum spanning tree for all regions*

---

**Description**

mst.all finds the set of connected regions that maximize the spatial scan statistic (the likelihood ratio test statistic) from each starting region, subject to relevant constraints. The function can be used to construct candidate zones for the dynamic minimum spanning tree (dmst), early stopping dynamic minimum spanning tree (edmst), double connected spatial scan test (dc), and maximum linkage (mlink) spatial scan test.

**Usage**

```
mst.all(
  neighbors,
  cases,
  pop,
  w,
  ex,
  ty,
  max_pop,
  type = "maxonly",
  nlinks = "one",
  early = FALSE,
  cl = NULL,
  progress = FALSE
)
```

**Arguments**

neighbors	A list containing the vector of neighbors for each region (in ascending order of distance from the region). The starting region itself is included among the neighbors.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ty	The total number of cases in the study area.
max_pop	The population upperbound (in total population) for a candidate zone.
type	One of "maxonly", "pruned", or "all". See Details.
nlinks	A character vector. The options are "one", "two", or "max". See Details.
early	A logical value indicating whether the "early" stopping criterion should be used. If TRUE, each sequence is stopped when the next potential zone doesn't produce a test statistic larger than the current zone. The default is FALSE.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
progress	A logical value indicating whether a progress bar should be displayed. The default is TRUE.

**Details**

This function is not intended to be used by users directly. Consequently, it prioritizes efficiency over user friendliness.

type is a character vector indicating what should be returned by the function. If type = "maxonly", then the maximum test statistic from each starting region is returned . If type = "pruned", the

function returns a list that includes the location ids, test statistic, total cases, expected cases, and total population for the zone with the maximum test statistic for each starting region. If `type = "all"`, the function returns a list of lists that includes the location ids, test statistic, total cases, expected cases, and total population for the sequence of candidate zones associated with each starting region. If `nlinks = "one"`, then a region only needs to be connected to one other region in the current zone to be considered for inclusion in the next zone. If `nlinks = "two"`, then the region must be connected to at least two other regions in the current zone. If `nlinks = "max"`, then only regions with the maximum number of connections to the current zone are considered for inclusion in the next zone.

### Value

Returns a list of relevant information. See Details.

### Author(s)

Joshua French

### References

Costa, M.A. and Assuncao, R.M. and Kulldorff, M. (2012) Constrained spanning tree algorithms for irregularly-shaped spatial clustering, *Computational Statistics & Data Analysis*, 56(6), 1771-1783. <doi:10.1016/j.csda.2011.11.001>

### Examples

```
# load data
data(nydf)
data(nyw)

# create relevant data
coords = nydf[,c("longitude", "latitude")]
cases = floor(nydf$cases)
pop = nydf$population
w = nyw
ex = sum(cases)/sum(pop)*pop
ubpop = 0.5
ubd = 0.5
ty = sum(cases) # total number of cases
# intercentroid distances
d = sp::spDists(as.matrix(coords), longlat = TRUE)
# upperbound for population in zone
max_pop = ubpop * sum(pop)
# upperbound for distance between centroids in zone
max_dist = ubd * max(d)
# create list of neighbors for each region
# (inclusive of region itself)
all_neighbors = nndist(d, ubd)
# find the dmst max zone
```

```
## Not run:
out = mst.all(all_neighbors, cases, pop, w, ex, ty, max_pop,
              type = "maxonly")
head(out)

out = mst.all(all_neighbors, cases, pop, w, ex, ty, max_pop,
              type = "pruned")
head(out)

## End(Not run)
```

---

mst.seq

*Minimum spanning tree sequence*

---

## Description

`mst.seq` finds the sequence of connected regions that maximize the spatial scan statistic (the likelihood ratio test statistic) from a starting region. The set of connected regions at each step is a candidate zone. The zone continues to grow until no region should be added to the zone due to relevant constraints (size, connectivity, or other stopping criteria). This function is not intended to be used by users directly, but it can be quite educational for seeing the spread of the cluster. Consequently, it prioritizes efficiency over user friendliness.

## Usage

```
mst.seq(
  start,
  neighbors,
  cases,
  pop,
  w,
  ex,
  ty,
  max_pop,
  type = "maxonly",
  nlinks = "one",
  early = FALSE
)
```

## Arguments

<code>start</code>	The initial region to start the candidate zone.
<code>neighbors</code>	A vector containing the neighbors for the starting region (in ascending order of distance from the region). The starting region itself is included among the neighbors.
<code>cases</code>	The number of cases observed in each region.
<code>pop</code>	The population size associated with each region.

w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
ty	The total number of cases in the study area.
max_pop	The population upperbound (in total population) for a candidate zone.
type	One of "maxonly", "pruned", or "all". The default is "maxonly". See Details.
nlinks	A character vector. The options are "one", "two", or "max". See Details.
early	A logical value indicating whether the "early" stopping criterion should be used. If TRUE, the sequence is stopped when the next potential zone doesn't produce a test statistic larger than the current zone. The default is FALSE.

### Details

The function can be used to construct candidate zones for the dynamic minimum spanning tree (dmst), early stopping dynamic minimum spanning tree (edmst), double connection spatial scan test (dc), and maximum linkage spatial scan test (mlink).

type is a character vector indicating what should be returned by the function. If type = "maxonly", then only the maximum of the log likelihood ratio test statistic across all candidate zones is returned. If type = "pruned", the function returns a list that includes the location ids, test statistic, total cases, expected cases, and total population for the zone with the maximum test statistic. If type = "all", the same information the same information is returned for the entire sequence of zones.

If nlinks = "one", then a region only needs to be connected to one other region in the current zone to be considered for inclusion in the next zone. If nlinks = "two", then the region must be connected to at least two other regions in the current zone. If nlinks = "max", then only regions with the maximum number of connections to the current zone are considered for inclusion in the next zone.

### Value

Returns a list of relevant information. See Details.

### Author(s)

Joshua French

### Examples

```
# load data
data(nydf)
data(nyw)

# create relevant data
coords = nydf[,c("longitude", "latitude")]
cases = floor(nydf$cases)
pop = nydf$population
w = nyw
ex = sum(cases)/sum(pop)*pop
ubpop = 0.5
```

```

ubd = 0.5
ty = sum(cases) # total number of cases
# intercentroid distances
d = sp::spDists(as.matrix(coords), longlat = TRUE)
# upperbound for population in zone
max_pop = ubpop * sum(pop)
# upperbound for distance between centroids in zone
max_dist = ubd * max(d)
# create list of neighbors for each region (inclusive of region itself)
all_neighbors = nndist(d, ubd)
# find the dmst max zone
mst.seq(start = 1, all_neighbors[[1]], cases, pop, w, ex,
        ty, max_pop)
mst.seq(start = 1, all_neighbors[[1]], cases, pop, w, ex,
        ty, max_pop, "pruned")
bigout = mst.seq(start = 1, all_neighbors[[1]], cases, pop,
                w, ex, ty, max_pop, "all")
head(bigout)

```

---

nn.cumsum

*Cumulative sum over nearest neighbors*

---

## Description

nn.cumsum computes the cumulative sum of y for the sequences of indices in each element of the list contained in nn.

## Usage

```
nn.cumsum(nn, y, simplify = TRUE)
```

## Arguments

nn	A list of nearest neighbors in the format produced by <a href="#">nnpop</a> .
y	A numeric vector of values to be summed over.
simplify	A logical value indicating whether the results should be simplified to a numeric vector. The default is TRUE.

## Value

A vector or list, depending on the value of simplify.

## Examples

```

# show nn.cumsum example for a circular scan setting
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
d = sp::spDists(coords, longlat = TRUE)

```

```

# compute circular nearest neighbors
nn = nnpop(d, pop = nydf$pop, ubpop = 0.1)
# compute cumulative sums over all nn
cnn = nn.cumsum(nn, cases)
# compute cumulative sums over just the first set of nn
cnn1 = cumsum(cases[nn[[1]]])
# check equality
all.equal(cnn1, cnn[seq_along(cnn1)])

```

---

nn2zones	<i>Convert nearest neighbors list to zones</i>
----------	--

---

### Description

nn2zones converts a list of nearest neighbors to a list of zones. The list of nearest neighbors will come from functions such as `nnpop` or `knn`.

### Usage

```
nn2zones(nn)
```

### Arguments

nn                    A list of nearest neighbors

### Value

A list of zones

### Examples

```

data(nydf)
coords = with(nydf, cbind(x, y))
nn = knn(coords, k = 2)
nn2zones(nn)

```

---

nndist	<i>Determine nearest neighbors based on maximum distance</i>
--------	--

---

### Description

nndist determines the nearest neighbors for a set of observations within a certain radius.

### Usage

```
nndist(d, ubd)
```

**Arguments**

d	An $n \times n$ square distance matrix containing the intercentroid distance between the $n$ region centroids.
ubd	A proportion in (0, 1]. The distance of potential clusters must be no more than $ubd * m$ , where $m$ is the maximum intercentroid distance between all coordinates.

**Details**

This function determines the nearest neighbors of each centroid based on the intercentroid distance. The number of nearest neighbors is limited by the furthest distance between the starting centroid and the farthest neighbor.

**Value**

Returns the indices of the nearest neighbors as a list.

**Author(s)**

Joshua French

**Examples**

```
data(nydf)
coords = as.matrix(nydf[,c("longitude", "latitude")])
d = as.matrix(dist(coords))
nn = nndist(d, ubd = 0.01)
```

---

nndup

*Determine duplicates in nearest neighbor list*

---

**Description**

nndup determines the indices of duplicated elements for a nearest neighbors list created by a function such as [nnpop](#) or [knn](#). The indices are related to the list returned by [nn2zones](#).

**Usage**

```
nndup(nn, N = max(unlist(nn)))
```

**Arguments**

nn	A list of nearest neighbors.
N	The largest value in nn.

**Value**

A logical vector of indicating duplicate indices.

**Examples**

```
nn = list(1:3, c(2:1, 4))
nndup(nn, 4)
```

---

nnpop

*Determine nearest neighbors with population constraint*

---

**Description**

scan.nn determines the nearest neighbors for a set of observations based on the distance matrix according to a population-based upperbound.

**Usage**

```
nnpop(d, pop, ubpop)

scan.nn(d, pop, ubpop)
```

**Arguments**

d	An $n \times n$ square distance matrix containing the intercentroid distance between the $n$ region centroids.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.

**Details**

This function determines the nearest neighbors of each centroid based on the intercentroid distance. The number of nearest neighbors is limited by the sum of the population values among the nearest neighbors. The set of nearest neighbors can contain no more than  $ubpop * \text{sum}(\text{pop})$  members of the population. The nearest neighbors are ordered from nearest to farthest.

**Value**

Returns the indices of the nearest neighbors as a list. For each element of the list, the indices are ordered from nearest to farthest from each centroid.

**Author(s)**

Joshua French

**Examples**

```
data(nydf)
coords = as.matrix(nydf[,c("longitude", "latitude")])
d = as.matrix(dist(coords))
nn = scan.nn(d, pop = nydf$pop, ubpop = 0.1)
```

---

noz	<i>Determine non-overlapping zones</i>
-----	--

---

### **Description**

Determine non-overlapping zones from a list of candidate zones.

### **Usage**

```
noz(x)
```

### **Arguments**

x                    A list containing the candidate zones.

### **Details**

The function takes a list of candidate zones. Each element of the list contains a candidate zones. The candidate zones are defined by the location indices of the regions comprising the zones. Starting with the first candidate zone, the function excludes every candidate zone that intersects the first (any other candidate zone that shares indices with the first zone). Moving onto the next non-overlapping candidate zone, the process is repeated. The function returns the indices (in the list of zones) of the zones that do not overlap.

### **Value**

A vector with the list indices of the non-overlapping zones.

### **Author(s)**

Joshua French

### **Examples**

```
x = list(1:2, 1:3, 4:5, 4:6, 7:8)
noz(x)
```

---

nydf

*Leukemia data for 281 regions in New York.*

---

### Description

This data set contains 281 observations related to leukemia cases in an 8 county area of the state of New York. The data were made available in Waller and Gotway (2005) and details are provided there. These data are related to a similar data set in Waller et al. (1994). The longitude and latitude coordinates are taken from the NYleukemia data set in the SpatialEpi package for plotting purposes.

### Usage

```
data(nydf)
```

### Format

A data frame with 281 rows and 4 columns:

**longitude** The longitude of the region centroid. These are NOT the original values provided by Waller and Gotway (2005), but are the right ones for plotting correctly.

**latitude** The latitude of the region centroid. These are NOT the original values provided by Waller and Gotway (2005), but are the right ones for plotting correctly.

**population** The population (1980 census) of the region.

**cases** The number of leukemia cases between 1978-1982.

**x** The original 'longitude' coordinate provided by Waller and Gotway (2005).

**y** The original 'latitude' coordinate provided by Waller and Gotway (2005).

---

nypoly

*SpatialPolygonsDataFrame for New York leukemia data.*

---

### Description

A `SpatialPolygonsDataFrame` for the New York leukemia data in `nydf`. Note that the coordinates in the polygon have been projected to a different coordinate system (UTM, zone 18), but the order of the regions/polygons is the same as in `nydf`.

### Usage

```
data(nypoly)
```

### Format

A `SpatialPolygonDataFrame`

### Source

---

nyw

*Adjacency matrix for New York leukemia data.*

---

### Description

This data set contains a 281 x 281 adjacency matrix for the New York leukemia data in `nydf`.

### Usage

```
data(nyw)
```

### Format

A matrix of dimension 281 x 281.

### Source

Waller, L.A. and Gotway, C.A. (2005). *Applied Spatial Statistics for Public Health Data*. Hoboken, NJ: Wiley.

### References

---

plot.smerc\_cluster      *Plot object of class smerc\_cluster.*

---

### Description

Plot clusters (the centroids of the regions in each cluster) in different colors. The most likely cluster is plotted with solid red circles by default. Points not in a cluster are black open circles. The other cluster points are plotted with different symbols and colors.

### Usage

```
## S3 method for class 'smerc_cluster'
plot(
  x,
  ...,
  nclusters = length(x$clusters),
  ccol = NULL,
  cpch = NULL,
  add = FALSE,
  usemap = FALSE,
  mapargs = list()
)
```

### Arguments

x	An object of class scan to be plotted.
...	Additional graphical parameters passed to the plot function.
nclusters	Number of clusters to plot.
ccol	Fill color of the plotted points. Default is <code>grDevices::hcl.colors(nclusters, palette = "viridis")</code> .
cpch	Plotting character to use for points in each cluster. Default is NULL, indicating <code>pch = 20</code> for the most likely cluster and then <code>pch = 2, 3, ...</code> , up to the remaining number of clusters.
add	A logical indicating whether results should be drawn on existing map.
usemap	Logical indicating whether the <code>maps::map</code> function should be used to create a plot background for the coordinates. Default is FALSE. Use TRUE if you have longitude/latitude coordinates.
mapargs	A list of arguments for the map function.

### Examples

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
out = scan.test(coords = coords, cases = floor(nydf$cases),
               pop = nydf$pop, nsim = 0,
```

```

        longlat = TRUE, alpha = 1)
plot(out, nclusters = 3)
## plot output for new york state
# specify desired argument values
mapargs = list(database = "county", region = "new york",
               xlim = range(out$coords[,1]),
               ylim = range(out$coords[,2]))
# needed for "county" database (unless you execute library(maps))
data(countyMapEnv, package = "maps")
plot(out, nclusters = 3, usemap = TRUE, mapargs = mapargs)

```

---

plot.tango

*Plots an object of class tango.*

---

### Description

Plots results of [tango.test](#). If Monte Carlo simulation was not used to produce `x`, then a density plot of the (approximate) null distribution of `tstat.chisq` is produced, along with a vertical line for the observed `tstat`. If a Monte Carlo test was used to produce `x`, then a scatterplot of the `gof.sim` versus `sa.sim` is compared to the observed values `gof` and `sa`, respectively.

### Usage

```

## S3 method for class 'tango'
plot(x, ..., obs.list = list(pch = 20), sim.list = list(pch = 2))

```

### Arguments

<code>x</code>	An object of class <code>tango</code> to be plotted.
<code>...</code>	Additional graphical parameters passed to plot function.
<code>obs.list</code>	A list containing arguments for the <a href="#">points</a> function, which is used to plot the <code>gof</code> and <code>sa</code> components, when appropriate.
<code>sim.list</code>	A list containing arguments for the <a href="#">points</a> function, which is used to plot the <code>gof.sim</code> and <code>sa.sim</code> components, when appropriate.

### See Also

[tango.test](#)

### Examples

```

data(nydf)
coords = as.matrix(nydf[,c("x", "y")])
w = dweights(coords, kappa = 1)
x1 = tango.test(nydf$cases, nydf$pop, w)
plot(x1)
x2 = tango.test(nydf$cases, nydf$pop, w, nsim = 49)
plot(x2)

```

---

```
print.smerc_cluster
```

*Print object of class smerc\_cluster.*

---

**Description**

Print smerc\_cluster object

**Usage**

```
## S3 method for class 'smerc_cluster'  
print(x, ..., extra = FALSE)
```

**Arguments**

x	An object of class smerc_cluster.
...	Arguments passed on to <code>base::print</code>
extra	A logical value. Default is FALSE. TRUE indicates that extra information should be printed.

**Examples**

```
data(nydf)  
coords = with(nydf, cbind(x, y))  
out = scan.test(coords = coords, cases = floor(nydf$cases),  
               pop = nydf$pop, nsim = 49,  
               longlat = TRUE, alpha = 0.12)  
  
out
```

---

```
print.tango
```

*Print object of class tango.*

---

**Description**

Print a tango object. If the crayon package is installed, then the results are printed in color.

**Usage**

```
## S3 method for class 'tango'  
print(x, ..., digits = 2)
```

**Arguments**

x	An object of class tango.
...	Arguments passed on to <code>base::print</code>
digits	Number of significant digits to print.

## Examples

```
data(nydf)
coords = as.matrix(nydf[,c("x", "y")])
w = dweights(coords, kappa = 1)
results = tango.test(nydf$cases, nydf$pop, w, nsim = 49)
results
```

---

rflex.midp

*Compute middle p-value*

---

## Description

Computes  $P(Y > \text{cases}) + P(Y = \text{cases})/2$  when  $Y \sim \text{Poisson}(\text{ex})$  or  $Y \sim \text{Binomial}(n = \text{pop}, p = \text{ex}/\text{pop})$ . This is middle p-value computed by Tango and Takahashi (2012).

## Usage

```
rflex.midp(cases, ex, type = "poisson", pop = NULL)
```

## Arguments

cases	The number of cases observed in each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
pop	The population size associated with each region.

## Value

A vector of middle p-values

## Author(s)

Joshua French

## References

Tango, T. and Takahashi, K. (2012), A flexible spatial scan statistic with a restricted likelihood ratio for detecting disease clusters. *Statist. Med.*, 31: 4207-4218. <doi:10.1002/sim.5478>

**Examples**

```

data(nydf)
cases = floor(nydf$cases)
pop = nydf$pop
ex = pop * sum(cases)/sum(pop)
# zones for poisson model
pp = rflex.midp(cases, ex)
# zones for binomial model
bp = rflex.midp(cases, ex, type = "binomial", pop = pop)

```

---

rflex.sim

*Perform rflex.test on simulated data*

---

**Description**

rflex.sim efficiently performs `rflex.test` on a simulated data set. The function is meant to be used internally by the `rflex.test` function, but is informative for better understanding the implementation of the test.

**Usage**

```

rflex.sim(
  nsim = 1,
  nn,
  w,
  ex,
  alpha1 = 0.2,
  type = "poisson",
  pop = NULL,
  cl = NULL
)

```

**Arguments**

nsim	A positive integer indicating the number of simulations to perform.
nn	A matrix of the k nearest neighbors for the regions described by w.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
alpha1	The middle p-value threshold.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
pop	The population size associated with each region.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

**Value**

A vector with the maximum test statistic for each simulated data set.

**Examples**

```
data(nydf)
data(nyw)
# determine knn
coords = with(nydf, cbind(longitude, latitude))
nn = knn(coords, longlat = TRUE, k = 50)
# determine expected number of cases in each region
cases = floor(nydf$cases)
pop = nydf$pop
ex = pop * sum(cases)/sum(pop)
tsim = rflex.sim(nsim = 5, nn = nn, w = nyw, ex = ex)
```

---

 rflex.test

---

*Restricted Flexibly-shaped Spatial Scan Test*

---

**Description**

rflex.test performs the restricted flexibly shaped spatial scan test of Tango and Takahashi (2012).

**Usage**

```
rflex.test(
  coords,
  cases,
  pop,
  w,
  k = 50,
  ex = sum(cases)/sum(pop) * pop,
  type = "poisson",
  nsim = 499,
  alpha = 0.1,
  longlat = FALSE,
  alpha1 = 0.2,
  cl = NULL
)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.

k	An integer indicating the maximum number of regions to include in a potential cluster. Default is 10
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
alpha1	The middle p-value threshold.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Details

The test is performed using the spatial scan test based on the Poisson test statistic and a fixed number of cases. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

### Value

Returns a list of length two of class `scan`. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the following components:

coords	The centroid of the significant clusters.
r	The radius of the window of the clusters.
pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

plot(nypoly, col = color.clusters(out))
```

---

rflex.zones

*Determine zones for flexibly shaped spatial scan test*

---

## Description

rflex.zones determines the unique zones to consider for the flexibly shaped spatial scan test of Tango and Takahashi (2012). The algorithm uses a breadth-first search to find all subgraphs connected to each vertex (region) in the data set of size  $k$  or less with the constraint that the middle  $p$ -value of each region must be less than  $\alpha_1$ .

## Usage

```
rflex.zones(
  nn,
  w,
  cases,
  ex,
  alpha1 = 0.2,
  type = "poisson",
  pop = NULL,
  cl = NULL,
  loop = FALSE,
  verbose = FALSE,
  pfreq = 1
)
```

**Arguments**

nn	An n by k matrix providing the k nearest neighbors of each region, presumably produced by the <a href="#">knn</a> function.
w	A binary spatial adjacency matrix for the regions.
cases	The number of cases observed in each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
alpha1	The middle p-value threshold.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
pop	The population size associated with each region. The default is NULL since this argument is only needed for type = "binomial".
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
loop	A logical value indicating whether a loop should be used to implement the function instead of <a href="#">pbapply</a> . The default is FALSE. If TRUE, then memory-saving steps are also taken.
verbose	A logical value indicating whether progress messages should be provided. The default is FALSE. If both loop and verbose are TRUE, informative messages are displayed that can be useful for diagnosing where the sequences of connected subgraphs are slowing down or having problems.
pfreq	The frequency that messages are reported from the loop (if verbose = TRUE). The default is pfreq = 1, meaning a message is returned for each index of the loop.

**Value**

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

scan.sim

*Perform scan.test on simulated data*

---

## Description

scan.sim efficiently performs [scan.test](#) on a simulated data set. The function is meant to be used internally by the [scan.test](#) function, but is informative for better understanding the implementation of the test.

## Usage

```

scan.sim(
  nsim = 1,
  nn,
  ty,
  ex,
  type = "poisson",
  ein = NULL,
  eout = NULL,
  tpop = NULL,
  popin = NULL,
  popout = NULL,
  cl = NULL,
  simdist = "multinomial",
  pop = NULL
)

```

**Arguments**

nsim	A positive integer indicating the number of simulations to perform.
nn	A list of nearest neighbors produced by <a href="#">nnpop</a> .
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be <code>ty - ein</code> and is computed automatically if not provided.
tpop	The total population in the study area.
popin	The total population in the zone.
popout	The population outside the zone. This should be <code>tpop - popin</code> and is computed automatically if not provided.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
simdist	Character string indicating the simulation distribution. The default is "multinomial", which conditions on the total number of cases observed. The other options are "poisson" and "binomial"
pop	The population size associated with each region.

**Value**

A vector with the maximum test statistic for each simulated data set.

**Examples**

```
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
d = sp::spDists(as.matrix(coords), longlat = TRUE)
nn = scan.nn(d, pop = nydf$pop, ubpop = 0.1)
cases = floor(nydf$cases)
ty = sum(cases)
ex = ty/sum(nydf$pop) * nydf$pop
yin = nn.cumsum(nn, cases)
ein = nn.cumsum(nn, ex)
tsim = scan.sim(nsim = 1, nn, ty, ex, ein = ein, eout = sum(ex) - ein)
```

---

scan.stat                      *Spatial scan statistic*

---

### Description

scan.stat calculates the spatial scan statistic for a zone (a set of spatial regions). The statistic is the log of the likelihood ratio test statistic of the chosen distribution. If type = "poisson" and a is more than zero, this statistic is penalized. See references.

### Usage

```
scan.stat(
  yin,
  ein = NULL,
  eout = NULL,
  ty,
  type = "poisson",
  popin = NULL,
  tpop = NULL,
  a = 0,
  shape = 1,
  yout = NULL,
  popout = NULL
)

stat.poisson(yin, yout, ein, eout, a = 0, shape = 1)

stat.binom(yin, yout, ty, popin, popout, tpop)
```

### Arguments

yin	The total number of cases in the zone.
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be $ty - ein$ and is computed automatically if not provided.
ty	The total number of cases in the study area.
type	The type of scan statistic to implement. The default choice are "poisson". The other choice is "binomial".
popin	The total population in the zone.
tpop	The total population in the study area.
a	A tuning parameter for the adjusted log-likelihood ratio. See details.
shape	The shape of the ellipse, which is the ratio of the length of the longest and shortest axes of the ellipse. The default is 1, meaning it is a circle.

yout	The observed number of cases outside the zone. This should be ty -yin and is computed automatically if not provided.
popout	The population outside the zone. This should be tpop -popin and is computed automatically if not provided.

**Value**

A vector of scan statistics.

**Author(s)**

Joshua French

**Examples**

```
# New York leukemia data
# total cases
ty = 552
# total population
tpop = 1057673

# poisson example with yin = 106 and ein = 62.13
scan.stat(yin = 106, ty = ty, ein = 62.13)
stat.poisson(yin = 106, yout = 552 - 106,
             ein = 62.13, eout = 552 - 62.13)

# binomial example with yin = 41 and popin = 38999
scan.stat(yin = 41, ty = ty,
          popin = 38999, tpop = tpop, type = "binomial")
stat.binom(41, ty - 41, ty, 38999, tpop - 38999, tpop)
```

## Description

scan.test performs the original spatial scan test of Kulldorf (1997) based on a fixed number of cases. Candidate zones are circular and extend from the observed region centroids. The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

## Usage

```
scan.test(
  coords,
  cases,
  pop,
  ex = sum(cases)/sum(pop) * pop,
  nsim = 499,
  alpha = 0.1,
  ubpop = 0.5,
  longlat = FALSE,
  cl = NULL,
  type = "poisson",
  min.cases = 2,
  simdist = "multinomial"
)
```

## Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <a href="#">makeCluster</a> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
min.cases	The minimum number of cases required for a cluster. The default is 2.

`simdist` Character string indicating the simulation distribution. The default is "multinomial", which conditions on the total number of cases observed. The other options are "poisson" and "binomial"

### Value

Returns a `smerc_cluster` object.

### Author(s)

Joshua French

### References

               pop = nydf$pop, nsim = 0,
               alpha = 1, longlat = TRUE)

## plot output for new york state
# specify desired argument values
mapargs = list(database = "county", region = "new york",
               xlim = range(out$coords[,1]), ylim = range(out$coords[,2]))
# needed for "state" database (unless you execute library(maps))
data(countyMapEnv, package = "maps")
plot(out, usemap = TRUE, mapargs = mapargs)

# a second example to match the results of Waller and Gotway (2005)
# in chapter 7 of their book (pp. 220-221).
# Note that the 'longitude' and 'latitude' used by them has
# been switched. When giving their input to SatScan, the coords
# were given in the order 'longitude' and 'latitude'.
# However, the SatScan program takes coordinates in the order
# 'latitude' and 'longitude', so the results are slightly different
# from the example above.
coords = with(nydf, cbind(y, x))
out2 = scan.test(coords = coords, cases = floor(nydf$cases),
                pop = nydf$pop, nsim = 0,
                alpha = 1, longlat = TRUE)
# the cases observed for the clusters in Waller and Gotway: 117, 47, 44
```

```
# the second set of results match
sget(out2$clusters, name = "cases")[1:3]
```

---

scan.zones	<i>Determine zones for the spatial scan test</i>
------------	--

---

## Description

scan.zones determines the unique candidate zones to consider for the circular spatial scan test of Kulldorff (1997).

## Usage

```
scan.zones(coords, pop, ubpop = 0.5, longlat = FALSE)
```

## Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.

## Value

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

## Author(s)

Joshua French

## References

Kulldorff, M. (1997) A spatial scan statistic. *Communications in Statistics - Theory and Methods*, 26(6): 1481-1496, <doi:10.1080/03610929708831995>

## Examples

```
data(nydf)
coords = cbind(nydf$longitude, nydf$latitude)
zones = scan.zones(coords = coords, pop = nydf$pop,
                  ubpop = 0.1, longlat = TRUE)
```

---

scan_stat	<i>Spatial scan statistic</i>
-----------	-------------------------------

---

### Description

scan\_stat calculates the spatial scan statistic for a zone (a set of spatial regions). The statistic is the log of the likelihood ratio test statistic of the chosen distribution. If type = "poisson" and a is more than zero, this statistic is penalized. See references.

### Usage

```
scan_stat(
  yin,
  ein = NULL,
  eout = NULL,
  ty,
  type = "poisson",
  popin = NULL,
  tpop = NULL,
  a = 0,
  shape = 1,
  yout = NULL,
  popout = NULL
)

stat_poisson(yin, yout, ein, eout, a = 0, shape = 1)

stat_binom(yin, yout, ty, popin, popout, tpop)
```

### Arguments

yin	The total number of cases in the zone.
ein	The expected number of cases in the zone. Conventionally, this is the estimated overall disease risk across the study area, multiplied by the total population size of the zone.
eout	The expected number of cases outside the zone. This should be ty -ein and is computed automatically if not provided.
ty	The total number of cases in the study area.
type	The type of scan statistic to implement. The default choice are "poisson". The other choice is "binomial".
popin	The total population in the zone.
tpop	The total population in the study area.
a	A tuning parameter for the adjusted log-likelihood ratio. See details.
shape	The shape of the ellipse, which is the ratio of the length of the longest and shortest axes of the ellipse. The default is 1, meaning it is a circle.

yout	The observed number of cases outside the zone. This should be ty -yin and is computed automatically if not provided.
popout	The population outside the zone. This should be tpop -popin and is computed automatically if not provided.

**Value**

A vector of scan statistics.

stat_poisson(yin = 106, yout = 552 - 106,
             ein = 62.13, eout = 552 - 62.13)

# binomial example with yin = 41 and popin = 38999
scan_stat(yin = 41, ty = ty,
          popin = 38999, tpop = tpop, type = "binomial")
stat_binom(41, ty - 41, ty, 38999, tpop - 38999, tpop)
```

---

sig\_noc

*Return most significant, non-overlapping zones*

---

**Description**

sig\_noc return the significant, non-overlapping zones order from most significant to least significant.

**Usage**

```
sig_noc(tobs, zones, pvalue, alpha, order_by = "tobs")
```

**Arguments**

tobs	The vector of observed test statistics for each zone
zones	A list of zones
pvalue	The p-value associated with each test statistic
alpha	The significance level of the test.
order_by	Either 'tobs' or 'pvalue', indicating the argument by which to order zones.

**Value**

A list with the significant, ordered, non-overlapping tobs, zones, pvalue., and idx (a vector with the relevant indices of the original zones).

**Examples**

```
tobs = c(1, 3, 2)
zones = list(1:2, 1:3, 2:3)
pvalue = c(0.5, 0.01, 0.02)
sig_noc(tobs, zones, pvalue, alpha = 0.05)
```

---

smerc

*smerc*

---

**Description**

*\*S\**tatistical *\*ME\**thods for *\*R\**egional *\*C\**ounts

---

smerc\_cluster

*Prepare smerc\_cluster*

---

**Description**

smerc\_cluster prepares a smerc\_cluster.

**Usage**

```
smerc_cluster(
  tobs,
  zones,
  pvalue,
  coords,
  cases,
  pop,
  ex,
  longlat,
  method,
  rel_param,
  alpha,
  w = NULL,
  d = NULL,
  a = NULL,
  shape_all = NULL,
  angle_all = NULL
)
```

**Arguments**

tobs	The vector of observed test statistics for each zone
zones	A list of zones
pvalue	The p-value associated with each test statistic
coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
method	A character string indicating the method used to construct the smerc_cluster.
rel_param	A names list with the relevant parameters associated with method.
alpha	The significance level of the test.
w	A binary spatial adjacency matrix for the regions.
d	A precomputed distance matrix based on coords
a	A single value $\geq 0$ indicating the penalty to use for <a href="#">elliptic.test</a> .
shape_all	A vector of shape parameters associated with zones.
angle_all	A vector of angle parameter associated with zones.

**Value**

A `smerc_cluster` object. The object generally has the following components:

<code>clusters</code>	A list containing information about the significant clusters. See further details below.
<code>coords</code>	The matrix of centroid coordinates.
<code>number_of_regions</code>	The number of regions considered.
<code>total_population</code>	The total population in the regions.
<code>total_cases</code>	The total number of cases in the regions.
<code>cases_per_100k</code>	The rate of cases per 100,000 persons.
<code>method</code>	The name of the method applied.
<code>rel_param</code>	A list of relevant method parameters.
<code>alpha</code>	The significance level.
<code>longlat</code>	A logical value indicating which type of distance was used.

Each element of the `clusters` component has:

<code>locids</code>	The ids of the regions in the cluster.
<code>centroid</code>	The cluster centroid.
<code>r</code>	The radius of the region (from the starting region to last region of the cluster).
<code>max_dist</code>	The maximum intercentroid distance between all the regions in the cluster.
<code>population</code>	The total population in the cluster.
<code>cases</code>	The number of cases in the cluster.
<code>expected</code>	The expected number of cases in the cluster.
<code>smr</code>	Standardized mortality ratio ( $\text{cases}/\text{expected}$ ) in the cluster.
<code>rr</code>	Relative risk in the cluster window. This is $(\text{cases}/\text{pop})/((\text{total\_cases} - \text{cases})/(\text{total\_population} - \text{population}))$ .
<code>loglikrat</code>	The log of the likelihood ratio test statistic for the cluster. Only valid for the scan-type tests.
<code>test_statistic</code>	The test statistic for the cluster.
<code>pvalue</code>	The p-value of the test statistic associated with the cluster.
<code>w</code>	The adjacency information for the cluster.

For `elliptic.test`, `clusters` additionally has:

<code>semiminor_axis</code>	The semi-minor axis length for the ellipse.
<code>semimajor_axis</code>	The semi-major axis length for the ellipse.
<code>angle</code>	The rotation angle of the ellipse.
<code>shape</code>	The shape of the ellipse.

---

summary.smerc\_cluster *Summary of smerc\_cluster object*

---

### Description

Summary of object of class smerc\_cluster.

### Usage

```
## S3 method for class 'smerc_cluster'
summary(object, ..., idx = seq_along(object$clusters), digits = 1)
```

### Arguments

object	An object of class smerc_cluster.
...	Arguments passed on to <a href="#">base::summary</a>
idx	A index vector indicating the elements of object\$clusters to print information for. The default is all clusters.
digits	Integer indicating the number of decimal places.

### Examples

```
data(nydf)
coords = with(nydf, cbind(x, y))
out = scan.test(coords = coords, cases = floor(nydf$cases),
               pop = nydf$pop, nsim = 49,
               longlat = TRUE, alpha = 0.12)
summary(out)
```

---

tango.stat *Tango's statistic*

---

### Description

tango.stat computes Tango's index (Tango, 1995), including both the goodness-of-fit and spatial autocorrelation components. See Waller and Gotway (2005).

### Usage

```
tango.stat(cases, pop, w)
```

**Arguments**

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	An $n \times n$ weights matrix.

**Value**

Returns a list with the test statistic (tstat), the goodness-of-fit component (gof), and the spatial autocorrelation component (sa).

**Author(s)**

Joshua French

**References**

Tango, T. (1995) A class of tests for detecting "general" and "focused" clustering of rare diseases. *Statistics in Medicine*. 14:2323-2334.

Waller, L.A. and Gotway, C.A. (2005). *Applied Spatial Statistics for Public Health Data*. Hoboken, NJ: Wiley.

**Examples**

```
data(nydf)
coords = as.matrix(nydf[,c("longitude", "latitude")])
w = dweights(coords, kappa = 1, type = "tango", longlat = TRUE)
tango.stat(nydf$cases, nydf$pop, w)
```

---

tango.test

*Tango's clustering detection test*

---

**Description**

tango.test performs a test for clustering proposed by Tango (1995). The test uses Tango's chi-square approximation for significance testing by default, but also uses Monto Carlo simulation when  $nsim > 0$ .

**Usage**

```
tango.test(cases, pop, w, nsim = 0)
```

**Arguments**

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	An $n \times n$ weights matrix.
nsim	The number of simulations for which to perform a Monto Carlo test of significance. Counts are simulated according to a multinomial distribution with $\text{sum}(\text{cases})$ total cases and class probabilities $\text{pop}/\text{sum}(\text{pop})$ . $\text{sum}(\text{cases})$ .

**Details**

The `dweights` function can be used to construct a weights matrix `w` using the method of Tango (1995), Rogerson (1999), or a basic style.

**Value**

Returns a list of class `tango` with elements:

tstat	Tango's index
tstat.chisq	The approximately chi-squared statistic proposed by Tango that is derived from <code>tstat</code>
dfc	The degrees of freedom of <code>tstat.chisq</code>
pvalue.chisq	The p-value associated with <code>tstat.chisq</code>
tstat.sim	The vector of test statistics from the simulated data if <code>nsim &gt; 0</code>
pvalue.sim	The p-value associated with the Monte Carlo test of significance when <code>nsim &gt; 0</code>

Additionally, the goodness-of-fit `gof` and spatial autocorrelation `sa` components of the Tango's index are provided (and for the simulated data sets also, if appropriate).

**See Also**

[dweights](#)

**Examples**

```
data(nydf)
coords = as.matrix(nydf[,c("x", "y")])
w = dweights(coords, kappa = 1)
results = tango.test(nydf$cases, nydf$pop, w, nsim = 49)
```

---

tango.weights	<i>Distance-based weights for tango.test</i>
---------------	--

---

**Description**

tango.weights constructs a distance-based weights matrix. The tango.weights function can be used to construct a weights matrix w using the method of Tango (1995), Rogerson (1999), or a basic style.

**Usage**

```
tango.weights(coords, kappa = 1, longlat = FALSE, type = "basic", pop = NULL)

dweights(coords, kappa = 1, longlat = FALSE, type = "basic", pop = NULL)
```

**Arguments**

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
kappa	A positive constant related to strength of spatial autocorrelation.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
type	The type of weights matrix to construct. Current options are "basic", "tango", and "rogerson". Default is "basic". See Details.
pop	The population size associated with each region.

**Details**

coords is used to construct an  $n \times n$  distance matrix d.

If type = "basic", then  $w_{ij} = \exp(-d_{ij}/\kappa)$ .

If type = "rogerson", then  $w_{ij} = \exp(-d_{ij}/\kappa) / \sqrt{(pop_i/pop * pop_j/pop)}$ .

If type = "tango", then  $w_{ij} = \exp(-4 * d_{ij}^2/\kappa^2)$ .

**Value**

Returns an  $n \times n$  matrix of weights.

**Author(s)**

Joshua French

## See Also

[tango.test](#)

## Examples

```
data(nydf)
coords = as.matrix(nydf[,c("longitude", "latitude")])
w = tango.weights(coords, kappa = 1, longlat = TRUE)
```

---

uls.sim

*Perform uls.test on simulated data*

---

## Description

uls.sim efficiently performs [uls.test](#) on a simulated data set. The function is meant to be used internally by the [uls.test](#) function, but is informative for better understanding the implementation of the test.

## Usage

```
uls.sim(
  nsim = 1,
  ty,
  ex,
  w,
  pop,
  ubpop,
  type = "poisson",
  check.unique = FALSE,
  cl = NULL
)
```

## Arguments

nsim	A positive integer indicating the number of simulations to perform.
ty	The total number of cases in the study area.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
w	A binary spatial adjacency matrix for the regions.

pop	The population size associated with each region.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
check.unique	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).

### Value

A vector with the maximum test statistic for each simulated data set.

### Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
pop = nydf$pop
ty = sum(cases)
ex = ty/sum(pop) * pop
tsim = uls.sim(1, ty, ex, nyw, pop = pop, ubpop = 0.5)
```

---

uls.test	<i>Upper Level Set Spatial Scan Test</i>
----------	--

---

### Description

`uls.test` performs the Upper Level Set (ULS) spatial scan test of Patil and Taillie (2004). The test is performed using the spatial scan test based on a fixed number of cases. The windows are based on the Upper Level Sets proposed by Patil and Taillie (2004). The clusters returned are non-overlapping, ordered from most significant to least significant. The first cluster is the most likely to be a cluster. If no significant clusters are found, then the most likely cluster is returned (along with a warning).

### Usage

```
uls.test(
  coords,
  cases,
  pop,
  w,
  ex = sum(cases)/sum(pop) * pop,
```

```

    nsim = 499,
    alpha = 0.1,
    ubpop = 0.5,
    longlat = FALSE,
    cl = NULL,
    type = "poisson",
    check.unique = FALSE
  )

```

## Arguments

coords	An $n \times 2$ matrix of centroid coordinates for the regions.
cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ex	The expected number of cases for each region. The default is calculated under the constant risk hypothesis.
nsim	The number of simulations from which to compute the p-value.
alpha	The significance level to determine whether a cluster is significant. Default is 0.10.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
longlat	The default is FALSE, which specifies that Euclidean distance should be used. If longlat is TRUE, then the great circle distance is used to calculate the inter-centroid distance.
cl	A cluster object created by <code>makeCluster</code> , or an integer to indicate number of child-processes (integer values are ignored on Windows) for parallel evaluations (see Details on performance).
type	The type of scan statistic to compute. The default is "poisson". The other choice is "binomial".
check.unique	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.

## Details

The ULS method has a special (and time consuming) construction when the observed rates aren't unique. This is unlikely to arise for real data, except with observed rates of 0, which are of little interest. The method can take substantially if this is considered.

## Value

Returns a list of length two of class scan. The first element (clusters) is a list containing the significant, non-overlapping clusters, and has the following components:

locids            The location ids of regions in a significant cluster.

pop	The total population in the cluster window.
cases	The observed number of cases in the cluster window.
expected	The expected number of cases in the cluster window.
smr	Standardized mortality ratio (observed/expected) in the cluster window.
rr	Relative risk in the cluster window.
loglikrat	The loglikelihood ratio for the cluster window (i.e., the log of the test statistic).
pvalue	The pvalue of the test statistic associated with the cluster window.

The second element of the list is the centroid coordinates. This is needed for plotting purposes.

### Examples

```
data(nydf)
data(nyw)
coords = with(nydf, cbind(longitude, latitude))
out = uls.test(coords = coords, cases = floor(nydf$cases),
              pop = nydf$pop, w = nyw,
              alpha = 0.05, longlat = TRUE,
              nsim = 9, ubpop = 0.5)
data(nypoly)
library(sp)
plot(nypoly, col = color.clusters(out))
```

---

uls.zones

*Determine sequence of ULS zones.*

---

### Description

uls.zones determines the unique zones obtained by implementing the ULS (Upper Level Set) test of Patil and Taillie (2004).

### Usage

```
uls.zones(cases, pop, w, ubpop = 0.5, check.unique = FALSE)
```

**Arguments**

cases	The number of cases observed in each region.
pop	The population size associated with each region.
w	A binary spatial adjacency matrix for the regions.
ubpop	The upperbound of the proportion of the total population to consider for a cluster.
check.unique	A logical value indicating whether a check for unique values should be determined. The default is FALSE. This is unlikely to make a practical difference for most real data sets.

**Details**

The zones returned must have a total population less than  $ubpop * \text{sum}(\text{pop})$  of all regions in the study area.

**Value**

Returns a list of zones to consider for clustering. Each element of the list contains a vector with the location ids of the regions in that zone.

**Author(s)**

Joshua French

**References**

Patil, G.P. & Taillie, C. Upper level set scan statistic for detecting arbitrarily shaped hotspots. *Environmental and Ecological Statistics* (2004) 11(2):183-197. <doi:10.1023/B:EEST.0000027208.48919.7e>

**Examples**

```
data(nydf)
data(nyw)
uls.zones(cases = nydf$cases, pop = nydf$population, w = nyw)
```

---

zones.sum

*Sum over zones*

---

**Description**

zones.sum computes the sum of y for the indices in each element of the list contained in zones.

**Usage**

```
zones.sum(zones, y)
```

**Arguments**

zones            A list of nearest neighbors in the format produced by [scan.zones](#).  
y                A numeric vector of values to be summed over.

**Value**

A numeric vector.

**Examples**

```
# show nn.cumsum example for a circular scan setting
data(nydf)
coords = with(nydf, cbind(longitude, latitude))
cases = floor(nydf$cases)
zones = scan.zones(coords, pop = nydf$pop, ubpop = 0.1)
# compute cumulative sums over all nn
szones = zones.sum(zones, cases)
# compute cumulative sums over just the first set of nn
szones2 = sapply(zones, function(x) sum(cases[x]))
# check equality
all.equal(szones, szones2)
```
